When partial discharge and overheating occurred inside SF$_6$ insulated electrical equipment, the status of SF$_6$ electrical equipment can be monitored and the development trend of insulation defect inside equipment can be expected through inspecting dissolved products. Raman spectra have more advantages compare with traditional SF$_6$ decomposition products inspection technique. Optimization of geometrical configuration of gas products and calculation of Raman spectra frequency are conducted in this research on the level of 6-31G (2df, p) basis set by utilizing The Density Functional Theory (DFT) and B3LYP method; and calculated shift is compared with actually measured shift of NIST. In addition, the relativity of calculated value and actually measured value of National Institute of Standards and Technology (NIST) is researched by utilizing correlation coefficient $R^2$ through linear regression. The result proves reliability of calculating Raman spectra of SF$_6$ decomposition gas product by DFT method and feasibility of using Raman spectra to qualitatively identify SF$_6$ decomposition gas products.

1. Introduction

Under the partial discharge and overheating condition of SF$_6$ insulated electrical equipment, SF$_6$ will dissolve and it will occur a series of complicated chemical reactions with micro-water and micro-oxygen inside the equipment (Belmadani et. al., 1991; Baldyga et al., 2017), which will finally generate SOF$_4$, SOF$_2$, SO$_2$F$_2$, S$_2$OF$_{10}$ and HF, SO$_2$ and other acid gases; if discharge is occurred around internal solid insulation, CF$_4$, SiF$_4$, CO, CO$_2$ may be generated (Shengchang et al., 2015). Therefore, operation status of SF$_6$ electrical equipment can be monitored and diagnostic identification can be expected through inspecting SF$_6$ decomposition gas products (Tang et al., 2012). Currently, gas chromatography method, gas sensor method, detector tube method, infrared spectroscopy method, photo acoustic spectrometry method and other empirical methods on SF$_6$ decomposition gas product are mainly adopted in China, but the performances are varied (Tang et. al., 2012).

Density functional theory (hereinafter referred to as DFT) has been frequently used to calculate characteristics, structures and energies of conformation theoretically (Wu et. al., 2016), and many literatures have reported analysis of structural information and mechanism of action by utilizing DFT (Liu et al., 2014, Gao et al., 2013, Jia et al., 2016, Sun et al., 2014, Li et al., 2016), and they can much more accurately expect geometry, chemical bond properties, vibration level, various spectra and other information of molecule.

Raman spectra has been widely applied in industrial production monitoring and control, petrochemical, environmental protection, food identification, geological analysis, gemstone identification, commodity inspection, medical science and other areas (Shuhuan et. al., 2015; Chen et al., 2016; Tregrossi et al., 2017). Compare with traditional inspection technique of SF$_6$ decomposition gas product, Raman spectra is advantageous in following aspects (Zhao, 2014).

In 2008, Li et al., from Shanghai Jiaotong University established a set of Raman inspection system of dissolved gas in transformer oil based on cavity enhancement method. In 2013, Somekawa et. al., from Japanese Institute of Laser Technology put forward a type of in-situ inspection method of dissolved gas in transformer oil based on Raman spectra which is unnecessary to separate oil and gas. In 2014, Chen et al., from Chongqing University established Raman spectra inspection platform of silver plated quartz glass tube to...
inspect 7 mixed gases dissolved in transformer oil. However, the research report on optimizing geometrical configuration and expecting Raman spectra of SF\textsubscript{6} decomposition gas product by applying DFT is rare.

2. Calculation Method

Gaussian 09 program package is adopted for theoretical calculation of this research, molecular model is constructed by Gauss View. Geometrical configuration optimization of many gas products, namely SO\textsubscript{2}F\textsubscript{2}, SOF\textsubscript{2}, SO\textsubscript{2}, and CF\textsubscript{4} molecule, is conducted respectively on the level of 6-31G (2df,p) basis set by utilizing DFT and B3LYP method. There no imaginary frequency in the calculation result, demonstrating that optimized structure is the minimum energy and the most stable structure of molecule. Calculate Raman frequency on the basis of optimized geometrical configuration (Jiangyan et. al., 2009) and compare calculated Raman shift with Raman shift actually measured by NIST.

3. Result and Discussion

3.1 Geometrical Configuration of SO\textsubscript{2}F\textsubscript{2} and Analysis of Simulation Result of Raman Spectra

SO\textsubscript{2}F\textsubscript{2} is the cone type of molecule. There is no imaginary frequency after optimization, the bond length is r(1,2)=r(1,3)=141.5 pm, r(1,4)=r(1,5)=155.4 pm and bond angle is θ(2,1,3)=125.1°, θ(2,1,4)=θ(2,1,5)=θ(3,1,4)=θ(3,1,5)=108.1° and θ(4,1,5)=95.3°. Refer to Figure 1 for its structure after optimization and its calculated Raman spectra.

![Molecular structure and calculated Raman spectra of SO\textsubscript{2}F\textsubscript{2}](image)

There are 9 vibration modes for SO\textsubscript{2}F\textsubscript{2} molecule, they all have Raman active and they are formed into 9 Raman peaks. The comparison between its calculated shift with that actually measured by NIST is shown in Table 1. It can be seen from table that between Raman peak of SO\textsubscript{2}F\textsubscript{2} actually measured by NIST and corresponding simulation result, the maximum deviation is 5.21% and the minimum deviation is 0.48%.

3.2 Geometrical Configuration of SOF₂ and Analysis of Simulation Result of Raman Spectra

SOF₂ is the quadrihedron type of molecule. There is also no imaginary frequency after optimization. The bond length is \( r(1,2)=143 \, \text{pm} \) and \( r(1,3)=r(1,4)=160.1 \, \text{pm} \). The bond angle is \( \theta(2,1,3)=\theta(2,1,4)=106.7^\circ \) and \( \theta(3,1,4)=93.1^\circ \). Refer to Figure 2 for structure of SOF₂ molecule and its calculated Raman spectra.

![Figure 2: Molecular Structure and Calculated Raman spectra of SOF₂.](image)

There are 6 vibration modes for SOF₂ molecule, they all have Raman active and they are formed into 6 Raman peaks. As shown in Table 2, it can be seen from table that between Raman peak of SOF₂ actually measured by NIST and corresponding simulation result, the maximum deviation is 5.62% and the minimum deviation is 0.05%.

3.3 Geometrical Configuration of SO₂ and Analysis of Simulation Result of Raman Spectra

SO₂ is the V-type molecule. After optimization, the bond length is \( r(1,2)=r(1,3)=143.7 \, \text{pm} \) and bond angle is \( \theta(2,1,3)=119.2^\circ \). Refer to Figure 3 for molecule structure of SO₂ and its calculated Raman spectra.

<td>1.37</td>
</tr>
</tbody>
</table>

There are 3 vibration modes for SO₂ molecule. As shown in Table 3, it can be seen from table that the maximum deviation is 1.72% and the minimum deviation is 0.52%.

3.4 Geometrical Configuration of CF₄ and Analysis of Simulation Result of Raman Spectra

CF₄ is the regular tetrahedron type of molecule. After optimization, the bond length is r(1,2)=r(1,3)=r(1,4)=r(1,5)=132.1 pm and bond angle is θ(2,1,3)=θ(2,1,4)=θ(2,1,5)=θ(3,1,4)=θ(3,1,5)=θ(4,1,5)=109.5°. Refer to Figure 4 for its structure and its calculated Raman spectra.

![Molecular Structure and Calculated Raman spectra of CF₄](image)

There are 9 vibration modes for CF₄ molecule, due to CF₄ molecule is symmetrical that different vibration modes may result in the same Raman shift. The comparison between its calculated shift with that actually measured by NIST is shown in Table 4. The maximum deviation is 1.21% and the minimum deviation is 0.71%.

</table>

In order to describe the relation between calculated value of Raman spectra and value actually measured by NIST more directly with calculated value as x shaft and actually measured value as y shaft to draw scatter diagram of peak value of Raman spectra of SO₂F₂, SOF₂, SO₃, and CF₄, conduct linear regression and calculate correlation coefficient R², just as Figure 5 shows.
4. Conclusions

Structural optimization and Raman spectra calculation of main SF₆ decomposition gas products of electrical equipment are conducted on the level of 6-31G (2df,p) basis set by utilizing DFT and B3LYP method in this research. In addition, calculated shift is compared with shift actually measured by NIST, and the relativity between theoretical calculated value and value actually measured by NIST of Raman spectra of SF₆ decomposition gas products is researched by utilizing correlation coefficient $R^2$ through linear regression. Following conclusions can be drawn:

Gained theoretically calculated Raman peak is greatly agreed with data actually measured by NIST as the value of correlation coefficient $R^2$ is 0.9993, verifying reliability of adopting DFT to calculate Raman spectra of SF₆ decomposition products.

This research lays a good foundation for quantitative inspection of SF₆ dissolved gases of electrical equipment based on Raman spectra technique.
