Deformations of granulated recuperative activated carbon AR-V (produced in granulated form from coal dust (coals mixture) and adhesion agents by steam treatment at the temperature of 1100 — 1200K) upon carbon tetrachloride adsorption has been studied. To solve this problem, a dilatometer was used. Its main part was a line differential transformer, the core of which was connected to the adsorbent by means of a rod. Any changes in the adsorbent height caused a change in the core position in the transformer, which influenced the signal recorded from its secondary winding. These results were compared with the adsorption isotherms. High sensitivity of the dilatometric method has been shown. The dilatometer used allowed the measurement of absolute deformations in the range 1·10⁻⁷ to 3·10⁻³ m.

1. Introduction

As early as (Meehan, 1927), it was established that solid bodies change their size when adsorbing gases or vapors. Even now, however, it has not yet been generally accepted that the adsorbent is being deformed, i.e., is not inert, in the process of adsorption. Nevertheless from a physical viewpoint it can be stated that there can be no inert adsorbents at all. In fact, if we consider the simplest adsorption on the flat uniform surface of an adsorbent, even here the surface tension of the adsorbent declines when adsorbate molecules interact with the surface atoms. Thus, the uncompensated force affecting the surface atoms of the adsorbent decreases and this causes deformation of the adsorbent. It is clear that the deformation degree will be different in different cases: it depends on the properties of particular adsorptive systems. Nevertheless, even minor deformations of the adsorbents contribute considerably to the total thermodynamic characteristics determined from adsorption and calorimetry experiments (Tvardovskiy, 2006). Despite this, direct measurements of adsorptive deformation essentially are not conducted nowadays.

Only measurements of structural characteristics of clay minerals (Tvardovskiy, 1997, 1999), (Calle, 1988), polymeric materials (Keller et al, 1999), (Zhang et al, 1997), carbons (Bangham, 1937), (Haines and McIntoe, 1947), (Wiig and
Juhola, 1949), (Yakovlev et al, 2003, 2004), (Fonkin et al, 2005) and zeolites (Krasilnikova and Kochirzhik, 1988) are performed.

For a long time the progress of research in this direction was hampered by the lack of theoretical concepts and by considerable experimental and methodical difficulties. However, studying the deformation of solids in the process of adsorption and absorption is of great importance, as mentioned, for both the progress of thermodynamics and practical applications.

This work presents the dilatometric investigations of the sorptive deformation of adsorbent AR-V upon carbon tetrachloride adsorption. To solve this problem, an inductive-type dilatometer was used.

2. Method, Results and Discussion

Deformation of the AR-V microporous carbon adsorbent during adsorption of CCl₄ in the temperature interval from 255.5 to 353 K and at pressures of 1-14·10⁵ Pa was studied.

The structure-energy characteristics of AR-V adsorbent were determined based on the adsorption isotherm of the standard benzene vapor at 293 K using the computational apparatus of Dubinin’s (1947) theory of the volumetric filling of micropores (TVFM). The following characteristics of the adsorbent sample were obtained: micropore volume \( \text{Wo} = 0.26 \text{ cm}^3/\text{g} \), characteristic energy of adsorption \( \text{E}_0 = 15.8 \text{kJ/mol} \), and characteristic micropore half-width \( \chi_0 = 0.76 \text{ nm} \).

An inductive-type dilatometer designed for measuring small deformations of solids during adsorption in pressure and temperature ranges of 1-2·10⁵ Pa and 77-570 K, respectively, was used. The scheme of the dilatometer is shown in Fig. 1: the core (7) of the induction converter (8) of linear displacements is connected with the rod (5) supported on the quartz plate (2), which is placed on the sample (3). The latter is placed inside the ampoule (4) between the quartz disks (2). The ampoule is connected to the dilatometer body through the screw (6). A change in the sample length results in the displacement of the core, which is detected by a digital voltmeter using a transformer. The dilatometer is connected to adsorption installation through a vacuum valve.

During experiments, the temperature in the dilatometer section containing the sample was held constant with an error of ±0.2 K. The rest volume of the dilatometer, along with the induction converter and the adsorption installation, was thermostatted in an air thermostat at 303 K.

The induction converter of displacements of the dilatometer was calibrated at 303 K using a set of standard plates with thicknesses of 0.01-1.00 mm. The dilatometer was adjusted to changes in temperature and gas pressure on a "model" of fused quartz analogous to the adsorbent sample in shape and sizes. The dilatometer used allowed measurement of absolute deformations in the range from 1·10⁻⁷ to 3·10⁻³ m. Absolute errors of relative linear adsorbent deformation, \( \Delta l / l \), if potted, did not exceed the linear size of the experimental points presented in Fig. 3.

Adsorption of CCl₄ was studied using a gravimetric vacuum adsorption installation with the electronic compensation of the weight change in three intervals with limits of 1, 10, and 100 mg. The error of measurement did not exceed 1 %. The gas pressure was
determined by M10 and M1000 pressure bellows gauges with measurement intervals of 1-1 \cdot 10^5 and 10-1.5 \cdot 10^5 \text{ Pa } and errors of \pm 0.1 \text{ and } \pm 1.0 \text{ Pa, respectively.}

Prior to the measurements, adsorbent AR-V were degassed by heating at corresponding temperatures in vacuum down to a residual pressure of 1.33 \cdot 10^{-3} \text{ Pa in the system. Carbon tetrachloride was thoroughly purified and dried, after } \text{CCl}_4 \text{ was degasses in vacuum, its vapor pressure corresponded to the tabular value.}

The isotherms of carbon tetrachloride vapor adsorption on dehydrated AR-V samples (Fig. 2) are S-shaped and characterized by narrow hysteresis loops in the relative pressure range P/P_s= 0.2-0.3. Initial parts of the isotherms are reversible.

The plots of the relative linear deformation of the AR-V carbon adsorbent as function of vapor pressure \text{CCl}_4 at temperatures from 255.5 to 353 K are presented in Fig. 3. As follows from the data in Fig. 3, the contraction of the sample achieves a value of 0.68\% at 353 K. At higher value of adsorption, the contraction is replaced by expansion. With the temperature decrease the effect of relative expansion increases from 0.17\% at 313 K to 0.78 \% at 255.5 K.

3. Conclusion

Deformation of activated carbon adsorbent AR-V upon CCl₄ adsorption has been studied. To solve this problem, a dilatometer was used. Its main part was a line differential transformer, the core of which was connected to the adsorbent by means of a
rod. Any changes in the adsorbent height caused a change in the core position in the transformer, which influenced the signal recorded from its secondary winding. These results were compared with the adsorption isotherms. High sensitivity of the dilatometric method has been shown. The dilatometer used allowed the measurement of absolute deformations in the range 1\times10^{-7} to 3\times10^{-3} m.
